# Message Passing Interface

George Bosilca bosilca@eecs.utk.edu

#### **MPI Standard**

- http://www.mpi-forum.org
- Current version: 2.2
- MPI = Message Passing Interface

# MPI Point-to-point communications

#### Send & Receive

- Explicit communications (FIFO per peer per communicator)
- Move data from one process to another (possibly local) process
  - The data is described by a data-type, a count and a memory location
  - The destination process by a rank in a communicator
  - The matching is tag based

```
int MPI_Send( void* buf, int count, MPI_Datatype datatype, int dest, int tag, MPI_Comm comm)
int MPI_Recv( void* buf, int count, MPI_Datatype datatype, int source, int tag, MPI_Comm comm, MPI_Status* status)
```

#### **Blocking Communications**

- The process is blocked in the MPI function until:
  - For receives the remote data has been safely copied into the receive buffer
  - For sends the send buffer can be safely modified by the user without impacting the message transfer

```
int MPI_Send( void* buf, int count, MPI_Datatype datatype, int dest, int tag, MPI_Comm comm)
int MPI_Recv( void* buf, int count, MPI_Datatype datatype, int source, int tag, MPI_Comm comm, MPI_Status* status)
```

#### Communication modes

- a send in **standard** mode can be started whether or not a matching receive has been posted. It may complete before a matching receive is posted.
  - successful completion of the send operation may depend on the occurrence of a matching receive
- Buffered mode send operation can be started whether or not a matching receive has been posted. It may complete before a matching receive is posted.
  - its completion does not depend on the occurrence of a matching receive
- send that uses the **Synchronous** mode can be started whether or not a matching receive was posted. It will complete successfully only if a matching receive is posted, and the receive operation has started to receive the message
  - Its completion does not only indicates that the send buffer can be reused, but it
    also indicates that the receiver started executing the matching receive

#### Communication modes

- send that uses the **Ready** communication mode may be started only if the matching receive is already posted. Otherwise, the operation is erroneous and its outcome is undefined.
  - completion of the send operation does not depend on the status of a matching receive, and merely indicates that the send buffer can be reused

	Buffered	Synchronous	Ready
Send	MPI_Bsend	MPI_Ssend	MPI_Rsend

# Semantics of Point-to-Point Communication

- Order: Messages are non-overtaking
- Progress: No progression guarantees except when in MPI calls
- Fairness: no guarantee of fairness.
   However, usually a best effort approach implemented in the MPI libraries.
- Resource limitations: Best effort

Quality implementation: a particular implementation of he standard, exhibiting a set of desired properties.

# Non-Blocking Communications

- The process returns from the call as soon as possible, before any data transfer has been initiated.
- All flavors of communication modes supported.
- Subsequent MPI call required to check the completion status.

```
int MPI_Isend( void* buf, int count, MPI_Datatype datatype, int dest, int tag, MPI_Comm comm,

MPI_Request *request)
int MPI_Irecv( void* buf, int count, MPI_Datatype datatype, int source, int tag, MPI_Comm comm,

MPI_Request *request)
```

- Single completion
  - completion of a send operation indicates that the sender is now free to update the locations in the send buffer
  - completion of a receive operation indicates that the receive buffer contains the received message

- Multiple Completions (ANY)
  - A call to MPI\_WAITANY or MPI\_TESTANY can be used to wait for the completion of one out of several operations.

- Multiple Completions (SOME)
  - A call to MPI\_WAITSOME or MPI\_TESTSOME can be used to wait for the completion of at least one out of several operations.

```
int MPI_Waitsome( int incount, MPI_Request *array_of_requests, int *outcount, int *array_of_indices, MPI_Status *array_of_statuses ) int MPI_Testsome( int incount, MPI_Request *array_of_requests, int *outcount, int *array_of_indices, MPI_Status *array_of_statuses )
```

- Multiple Completions (ALL)
  - A call to MPI\_WAITALL or MPI\_TESTALL can be used to wait for the completion of all operations.

```
int MPI_Waitsome( int count, MPI_Request *array_of_requests, MPI_Status *array_of_statuses ) int MPI_Testall( int count, MPI_Request *array_of_requests, int *flag, MPI_Status *array_of_statuses )
```

#### Persistent Communications

- A communication with the same argument list repeatedly executed within the inner loop of a parallel computation
  - Allow MPI implementations to optimize the data transfers
- All communication modes (buffered, synchronous and ready) can be applied

```
int MPI_Send_init( void* buf, int count, MPI_Datatype datatype, int dest, int tag, MPI_Comm comm,

MPI_Request *request)
int MPI_Recv_init( void* buf, int count, MPI_Datatype datatype, int source, int tag, MPI_Comm comm,

MPI_Request *request)
```

# MPI Derived Datatypes

#### **MPI** Datatypes

- Abstract representation of underlying data
  - Handle type: MPI\_Datatype
- Pre-defined handles for intrinsic types
  - E.g., C: MPI\_INT, MPI\_FLOAT,MPI\_DOUBLE
  - E.g., Fortran: MPI\_INTEGER, MPI\_REAL
  - E.g., C++: MPI::BOOL
- User-defined datatypes
  - E.g., arbitrary / user-defined C structs

#### MPI Data Representation

- Multi platform interoperability
- Multi languages interoperability
  - Is MPI\_INT the same as MPI\_INTEGER?
  - How about MPI\_INTEGER[1,2,4,8]?
- Handling datatypes in Fortran with MPI\_SIZEOF and MPI\_TYPE\_MATCH\_SIZE

# Multi-Platform Interoperability

- Different data representations
  - Length 32 vs. 64 bits
  - Endianness conflict
- Problems
  - No standard about the data length in the programming languages (C/C++)
  - No standard floating point data representation
    - IEEE Standard 754 Floating Point Numbers
      - Subnormals, infinities, NANs ...
    - Same representation but different lengths

#### **How About Performance?**

- Old way
  - Manually copy the data in a user pre-allocated buffer, or
  - Manually use MPI\_PACK and MPI\_UNPACK
- New way
  - Trust the [modern] MPI library
  - High performance MPI datatypes

#### MPI Datatypes

- MPI uses "datatypes" to:
  - Efficiently represent and transfer data
  - Minimize memory usage
- Even between heterogeneous systems
  - Used in most communication functions (MPI\_SEND, MPI\_RECV, etc.)
  - And file operations
- MPI contains a large number of predefined datatypes

# Some of MPI's Pre-Defined Datatypes

MPI_Datatype	C datatype	Fortran datatype
MPI_CHAR	signed char	CHARACTER
MPI_SHORT	signed short int	INTEGER*2
MPI_INT	signed int	INTEGER
MPI_LONG	signed long int	
MPI_UNSIGNED_CHAR	unsigned char	
MPI_UNSIGNED_SHORT	unsigned short	
MPI_UNSIGNED	unsigned int	
MPI_UNSIGNED_LONG	unsigned long int	
MPI_FLOAT	float	REAL
MPI_DOUBLE	double	DOUBLE PRECISION
MPI_LONG_DOUBLE	long double	DOUBLE PRECISION*8

# Datatype Matching

- Two requirements for correctness:
  - Type of each data in the send / recv buffer matches the corresponding type specified in the sending / receiving operation
  - Type specified by the sending operation has to match the type specified for receiving operation
- Issues:
  - Matching of type of the host language
  - Match of types at sender and receiver

#### **Datatype Conversion**

- "Data sent = data received"
- 2 types of conversions:
  - Representation conversion: change the binary representation (e.g., hex floating point to IEEE floating point)
  - Type conversion: convert from different types (e.g., int to float)
- Only representation conversion is allowed

#### **Datatype Conversion**

```
if( my_rank == root )
    MPI_Send( ai, 1, MPI_INT, ... )
else
    MPI_Recv( ai, 1, MPI_INT, ... )
```

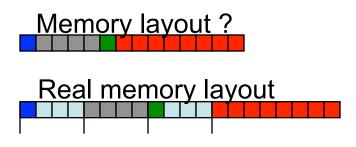

```
if( my_rank == root )
    MPI_Send( ai, 1, MPI_INT, ... )
else
    MPI_Recv( af, 1, MPI_FLOAT, ... )
```

# Memory Layout

How to describe a memory layout?

```
struct {
 char c1;
 int i;
 char c2;
 double d;
}
```

Using iovecs (list of addresses)
<pointer to memory, length>
<br/>

<addr\_of\_c2, 1>, <addr\_of\_l, 4>, <addr\_of\_d, 8>

- Waste of space
- Not portable ...

Using displacements from base addr <a href="displacement"><a href="displacement"><a href="displacement">displacement</a>, length>

- Sometimes more space efficient
- And nearly portable
- •What are we missing?

#### Datatype Specifications

- Type signature
  - Used for message matching { type<sub>0</sub>, type<sub>1</sub>, ..., type<sub>n</sub> }
- Type map
  - Used for local operations { (type<sub>0</sub>, disp<sub>0</sub>), (type<sub>1</sub>, disp<sub>1</sub>),..., (type<sub>n</sub>, disp<sub>n</sub>) }

It's all about the memory layout

# **User-Defined Datatypes**

- Applications can define unique datatypes
  - Composition of other datatypes
  - MPI functions provided for common patterns
    - Contiguous
    - Vector
    - Indexed
    - •
- Always reduces to a type map of predefined datatypes

#### Handling datatypes

- MPI impose that all datatypes used in communications or file operations should be committed.
  - Allow MPI libraries to optimize the data representation

```
MPI_Type_commit( MPI_Datatype* )
MPI_Type_free( MPI_Datatype* )
```

 All datatypes used during intermediary steps, and never used to communicate does not need to be committed.

#### Contiguous Blocks

Replication of the datatype into contiguous locations.

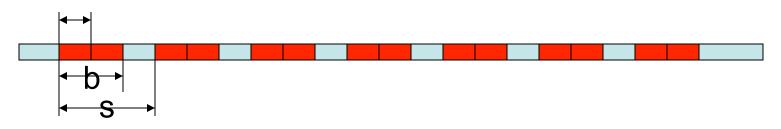

```
MPI_Type_contiguous(3, oldtype, newtype)
```

```
MPI_TYPE_CONTIGUOUS( count, oldtype, newtype )
IN count replication count( positive integer)
IN oldtype old datatype (MPI_Datatype handle)
OUT newtype new datatype (MPI_Datatype handle)
```

#### Vectors

 Replication of a datatype into locations that consist of equally spaced blocks

MPI\_Type\_vector(7, 2, 3, oldtype, newtype)

```
MPI_TYPE_VECTOR( count, blocklength, stride, oldtype, newtype )
IN count number of blocks (positive integer)
IN blocklength number of elements in each block (positive integer)
IN stride number of elements between start of each block (integer)
IN oldtype old datatype (MPI_Datatype handle)
OUT newtype new datatype (MPI_Datatype handle)
```

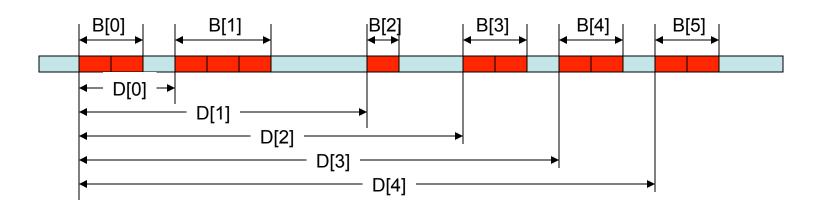

#### Indexed Blocks

 Replication of an old datatype into a sequence of blocks, where each block can contain a different number of copies and have a different displacement

```
MPI_TYPE_INDEXED( count, array_of_blocks, array_of_displs, oldtype, newtype )
                 number of blocks (positive integer)
IN
     count
                 number of elements per block (array of positive integer)
    a_of_b
IN
IN
                 displacement of each block from the beginning in multiple multiple
    a_of_d
                       of oldtype (array of integers)
     oldtype
                 old datatype (MPI_Datatype handle)
IN
OUT newtype
                 new datatype (MPI_Datatype handle)
```

#### Indexed Blocks

```
array_of_blocklengths[] = { 2, 3, 1, 2, 2, 2 }
array_of_displs[] = { 0, 3, 10, 13, 16, 19 }
MPI_Type_indexed( 6, array_of_blocklengths,
array_of_displs, oldtype, newtype )
```

#### **Datatype Composition**

- Each of the previous functions are the super set of the previous
   CONTIGUOUS < VECTOR < INDEXED</li>
- Extend the description of the datatype by allowing more complex memory layout
  - Not all data structures fit in common patterns
  - Not all data structures can be described as compositions of others

#### "H" Functions

- Displacement is not in multiple of another datatype
- Instead, displacement is in bytes
  - MPI\_TYPE\_HVECTOR
  - MPI TYPE HINDEX
- Otherwise, similar to their non-"H" counterparts

#### **Arbitrary Structures**

- The most general datatype constructor
- Allows each block to consist of replication of different datatypes

```
MPI_TYPE_CREATE_STRUCT( count, array_of_blocklength,
                      array_of_displs, array_of_types, newtype)
              number of entries in each array (positive integer)
IN
     count
    a_of_b
              number of elements in each block (array of integers)
IN
    a_of_d
              byte displacement in each block (array of Aint)
IN
              type of elements in each block (array of MPI Datatype handle)
IN
     a of t
OUT newtype
               new datatype (MPI_Datatype handle)
```

#### **Arbitrary Structures**

```
struct {
                Array_of_lengths[] = { 2, 1 };
 int i[3];
                Array_of_displs[] = { 0, 3*sizeof(int) };
 float f[2];
} array[100];
                Array_of_types[] = { MPI_INT, MPI_FLOAT };
                MPI_Type_struct( 2, array_of_lengths,
                  array_of_displs, array_of_types, newtype);
                                           float
                                                       float
       int
                   int
                               int
      length[0]
                                         length[1]
     displs[0]
                                         displs[1]
```

# Portable Vs. non portable

- The portability refer to the architecture boundaries
- Non portable datatype constructors:
  - All constructors using byte displacements
  - All constructors with H<type>,MPI\_Type\_struct
- Limitations for non portable datatypes
  - One sided operations
  - Parallel I/O operations

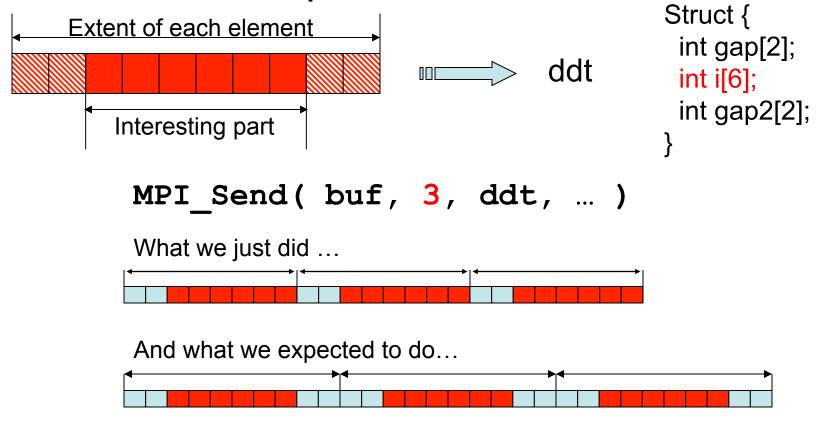

## MPI\_GET\_ADDRESS

- Allow all languages to compute displacements
  - Necessary in Fortran
  - Usually unnecessary in C (e.g., "&foo")

```
MPI_GET_ADDRESS( location, address )IN location location in the caller memory (choice)OUT address address of location (address integer)
```

#### And Now the Dark Side...

 Sometimes more complex memory layout have to be expressed

# Lower-Bound and Upper-Bound Markers

- Define datatypes with "holes" at the beginning or end
- 2 pseudo-types: MPI\_LB and MPI\_UB
  - Used with MPI\_TYPE\_STRUCT

```
Typemap = { (type_0, disp_0), ..., (type_n, disp_n) }
```

### MPI LB and MPI UB

```
displs = (-3, 0, 6)
blocklengths = (1, 1, 1)
types = ( MPI LB, MPI INT, MPI UB )
MPI Type struct(3, displs, blocklengths,
  types, type1 )
                    Typemap= \{ (lb, -3), (int, 0), (ub, 6) \}
MPI Type contiguous (3, type1, type2)
             Typemap= { (lb, -3), (int, 0), (int, 9), (int, 18), (ub, 24) }
```

#### MPI 2 Solution

- Problem with the way MPI-1 treats this problem: upper and lower bound can become messy, if you have derived datatype consisting of derived dataype consisting of derived datatype consisting of... and each of them has MPI\_UB and MPI\_LB set
- There is no way to erase LB and UB markers once they are set !!!
- MPI-2 solution: reset the extent of the datatype

```
MPI_Type_create_resized ( MPI_Datatype datatype, MPI_Aint lb, MPI_Aint extent, MPI_Datatype*newtype );
```

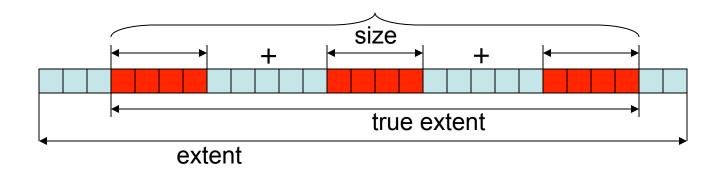

Erases all previous lb und ub markers

# True Lower-Bound and True Upper-Bound Markers

- Define the real extent of the datatype: the amount of memory needed to copy the datatype inside
- TRUE\_LB define the lower-bound ignoring all the MPI\_LB markers.

```
\begin{aligned} & \text{Typemap} = \{ \text{ (type}_0, \text{ disp}_0), \dots, \text{ (type}_n, \text{ disp}_n) \} \\ & \text{true\_lb(Typemap)} = \min_j \{ \text{ disp}_j & \text{: type}_j \text{ != lb } \} \\ & \text{true\_ub(Typemap)} = \max_j \{ \text{ disp}_j + \text{ sizeof(type}_i) : \text{ type}_i \text{ != ub } \} \end{aligned}
```

# Information About Datatypes

```
MPI_TYPE_GET_{TRUE_}EXTENT( datatype, {true_}lb, {true_}extent )
IN datatype the datatype (MPI_Datatype handle)
OUT {true_}lb {true} lower-bound of datatype (MPI_AINT)
OUT {true_}extent {true} extent of datatype (MPI_AINT)
MPI_TYPE_SIZE( datatype, size)
IN datatype the datatype (MPI_Datatype handle)
OUT size datatype size (integer)
```

# Decoding a datatype

- Sometimes is important to know how a datatype was created (eg. Libraries developers)
- Given a datatype can I determine how it was created?
- Given a datatype can I determine what memory layout it describe?

# MPI\_Type\_get\_enveloppe

```
MPI_Type_get_envelope ( MPI_Datatype datatype,
int *num_integers, int *num_addresses,
int *num_datatypes, int *combiner );
```

- The combiner field returns how the datatype was created, e.g.
  - MPI COMBINER NAMED: basic datatype
  - MPI\_COMBINER\_CONTIGUOS: MPI\_Type\_contiguous
  - MPI\_COMBINER\_VECTOR: MPI\_Type\_vector
  - MPI\_COMBINER\_INDEXED: MPI\_Type\_indexed
  - MPI\_COMBINER\_STRUCT: MPI\_Type\_struct
- The other fields indicate how large the integer-array, the datatypearray, and the address-array has to be for the following call to MPI\_Type\_get\_contents

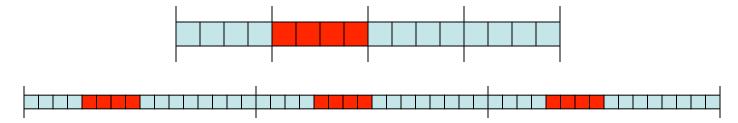

## MPI\_Type\_get\_contents

MPI\_Type\_get\_contents ( MPI\_Datatype datatype,
 int max\_integer, int max\_addresses, int max\_datatypes,
 int \*integers, int \*addresses, MPI\_Datatype \*dts);

- Call is erroneous for a predefined datatypes
- If returned data types are derived datatypes, then objects are duplicates of the original derived datatypes.
   User has to free them using MPI Type free
- The values in the integers, addresses and datatype arrays are depending on the original datatype constructor

# One Data By Cache Line

- Imagine the following architecture:
  - Integer size is 4 bytes
  - Cache line is 16 bytes
- We want to create a datatype containing the second integer from each cache line, repeated three times

How many ways are there?

#### Solution 1

```
MPI_Datatype array_of_types[] = { MPI_INT, MPI_INT, MPI_INT, MPI_UB };
MPI_Aint start, array_of_displs[] = { 0, 0, 0, 0 };
int array_of_lengths[] = { 1, 1, 1, 1 };
struct one by cacheline c[4];
MPI_Get_address( &c[0], &(start) );
MPI Get address( &c[0].int[1], &(array of displs[0]) );
MPI_Get_address( &c[1].int[1], &(array_of_displs[1]) );
MPI_Get_address( &c[2].int[1], &(array_of_displs[2]) );
MPI Get address(&c[3], &(array of displs[3]));
for(i = 0; i < 4; i++) Array of displs[i] -= start;
MPI_Type_create_struct( 4, array_of_lengths,
                         array_of_displs, array_of_types, newtype)
                                   newtype
```

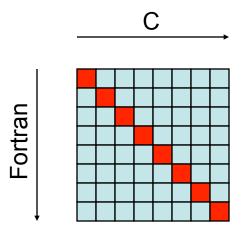

#### Solution 2

```
MPI_Datatype array_of_types[] = { MPI_INT, MPI_UB };
MPI_Aint start, array_of_displs[] = { 4, 16 };
int array_of_lengths[] = { 1, 1 };
struct one by cacheline c[2];
MPI_Get_address( &c[0], &(start) );
MPI_Get_address( &c[0].int[1], &(array_of_displs[0]) );
MPI_Get_address( &c[1], &(array_of_displs[1]) );
Array_of_displs[0] -= start;
Array_of_displs[1] -= start;
MPI_Type_create_struct( 2, array_of_lengths,
             array_of_displs, array_of_types, temp_type )
MPI Type contiguous (3, temp type, newtype)
                                    newtype
```

temp\_type

#### Exercise

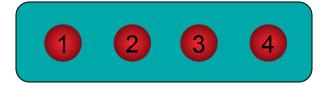

- Goals:
  - Create a datatype describing a matrix diagonal
  - What's different between C and Fortran?

# Intra and Inter Communicators

- A group is a set of processes
  - The group have a size
  - And each process have a rank
- Creating a group is a local operation
- Why we need groups
  - To make a clear distinction between processes
  - To allow communications in-between subsets of processes
  - To create intra and inter communicators ...

- MPI\_GROUP\_\*( group1, group2, newgroup)
  - Where \* ∈ {UNION, INTERSECTION, DIFFERENCE}
  - Newgroup contain the processes satisfying the \*
     operation ordered first depending on the order in
     group1 and then depending on the order in group2.
  - In the newgroup each process could be present only one time.
- There is a special group without any processes MPI\_GROUP\_EMPTY.

- group1 = {a, b, c, d, e}
- group2 = {e, f, g, b, a}
- Union
  - newgroup = {a, b, c, d, e, f, g}
- Difference
  - newgroup = {c, d}
- Intersection
  - newgroup =  $\{a, b, e\}$

- MPI\_GROUP\_\*(group, n, ranks, newgroup)
  - Where  $* \in \{INCL, EXCL\}$
  - N is the number of valid indexes in the ranks array.
- For INCL the order in the result group depend on the ranks order
- For EXCL the order in the result group depend on the original order

- Group = {a, b, c, d, e, f, g, h, i, j}
- N = 4, ranks =  $\{3, 4, 1, 5\}$
- INCL
  - Newgroup = {c, d, a, e}
- EXCL
  - Newgroup = {b, c, f, g, h, i, j}

- MPI\_GROUP\_RANGE\_\*(group, n, ranges, newgroup)
  - Where \* ∈ {INCL, EXCL}
  - N is the number of valid entries in the ranges array
  - Ranges is a tuple (start, end, stride)
- For INCL the order in the new group depend on the order in ranges
- For EXCL the order in the new group depend on the original order

- Group = {a, b, c, d, e, f, g, h, i, j}
- N=3; ranges = ((6, 7, 1), (1, 6, 2), (0, 9, 4))
- Then the range

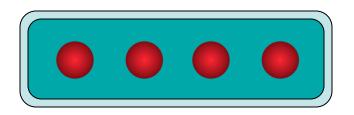

```
-(6, 7, 1) => \{g, h\} (ranks (6, 7))
```

- $-(1, 6, 2) => \{b, d, f\} (ranks (1, 3, 5))$
- $-(0, 9, 4) => \{a, e, i\} (ranks (0, 4, 8))$
- INCL
  - Newgroup =  $\{g, h, b, d, f, a, e, i\}$
- EXCL
  - Newgroup = {c, j}

#### Communicators

- A special channel between some processes used to exchange messages.
- Operations creating the communicators are collectives, but accessing the communicator information is a local operation.
- Special communicators: MPI\_COMM\_WORLD, MPI\_COMM\_NULL, MPI\_COMM\_SELF
- MPI\_COMM\_DUP(comm, newcomm) create an identical copy of the comm in newcomm.
  - Allow exchanging messages between the same set of nodes using identical tags (useful for developing libraries).

What exactly is a intracommunicator?

- some processes
- ONE group
- one communicator
- MPI\_COMM\_SIZE, MPI\_COMM\_RANK
- MPI\_COMM\_COMPARE( conn1, comm2, result)
  - MPI\_IDENT: comm1 and comm2 represent the same communicator
  - MPI\_CONGRUENT: same processes, same ranks
  - MPI\_SIMILAR: same processes, different ranks
  - MPI UNEQUAL: otherwise

- MPI\_COMM\_CREATE( comm, group, newcomm)
  - Create a new communicator on all processes from the communicator comm who are defined on the group.
  - All others processes get MPI\_COMM\_NULL

```
MPI_Group_range_excl( group, 1, (0, 9, 2), odd_group );
MPI_Group_range_excl( group, 1, (1, 9, 2), even_group );
MPI_Comm_create( comm, odd_comm, odd_comm );
MPI_Comm_create( comm, even_group, even_comm );
```

- MPI\_COMM\_SPLIT( comm, color, key, newcomm )
  - Color : control of subset assignment
  - Key: control of rank assignement

rank	0	1	2	3	4	5	6	7	8	9
process	Α	В	С	D	E	F	G	Н	I	J
color	0	T	3	0	3	0	0	5	3	T
key	3	1	2	5	1	1	1	2	1	0

3 different colors => 3 communicators

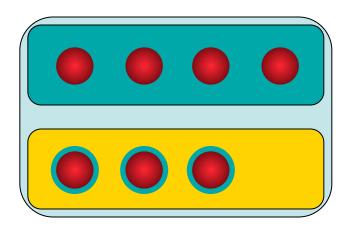

- 1.  $\{A, D, F, G\}$  with ranks  $\{3, 5, 1, 1\} = \{F, G, A, D\}$
- 2.  $\{C, E, I\}$  with ranks  $\{2, 1, 3\}$  =>  $\{E, I, C\}$
- 3.  $\{H\}$  with ranks  $\{1\}$  =>  $\{H\}$

B and J get MPI\_COMM\_NULL as they provide an undefined color (MPI\_UNDEFINED)

 $\begin{array}{c|c}
0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 \\
\hline
0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 \\
\hline
1 & 3 & 5 & 7 & 9 & 7 & 9 & 7 & 9 & 7 & 9 & 7 \\
\end{array}$ 

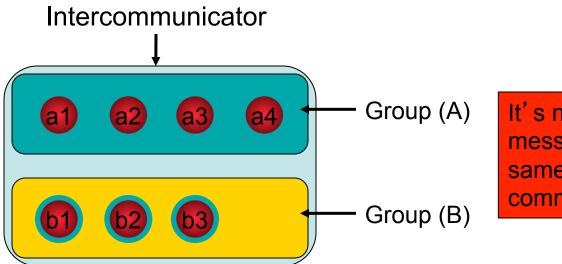

Rank	0	1	2	3	4	5	6	7	8	9
process	Α	В	С	D	Ш	F	G	Ι	I	J
Color	0	1	0	1	0	1	0	1	0	1
Key	1	1	1	1	1	1	1	1	1	1

And what's a intercommunicator?

- some more processes
- TWO groups
- one communicator
- MPI\_COMM\_REMOTE\_SIZE(comm, size)
   MPI\_COMM\_REMOTE\_GROUP(comm, group)
- MPI\_COMM\_TEST\_INTER(comm, flag)
- MPI\_COMM\_SIZE, MPI\_COMM\_RANK return the local size respectively rank

### Anatomy of a Intercommunicator

It's not possible to send a message to a process in the same group using this communicator

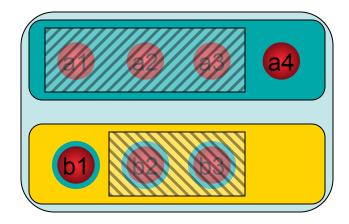

For any processes from group (A)

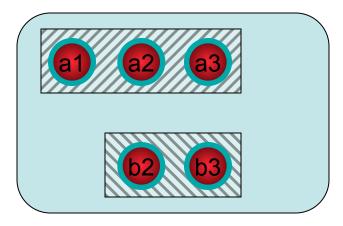

- (A) is the local group
- (B) is the remote group

For any processes from group (B)

- (A) is the remote group
- (B) is the local group

- MPI\_COMM\_CREATE(comm, group, newcomm)
  - All processes on the left group should execute the call with the same subgroup of processes, when all processes from the right side should execute the call with the same subgroup of processes. Each of the subgroup is related to a different side.

 MPI\_INTERCOMM\_CREATE(local\_comm, local\_leader, bridge\_comm, remote\_leader, tag, newintercomm)

Local\_comm : local intracommunicator

Local\_leader : rank of root in the local\_comm

Bridge\_comm: "bridge" communicator ...

Remote\_leader : rank of remote leader in bridge\_comm

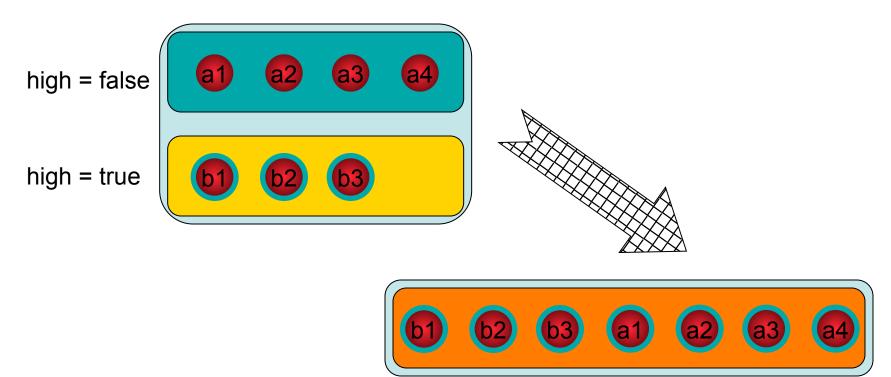

MPI\_INTERCOMM\_CREATE

Ica, 0, lb, 2, tag, new

Icb, 4, Ib, 1, tag, new

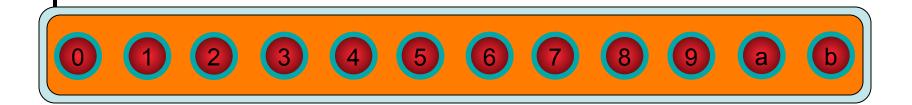

- MPI\_INTERCOMM\_MERGE(intercomm, high, intracomm)
  - Create an intracomm from the union of the two groups
  - The order of processes in the union respect the original one
  - The high argument is used to decide which group will be first (rank 0)

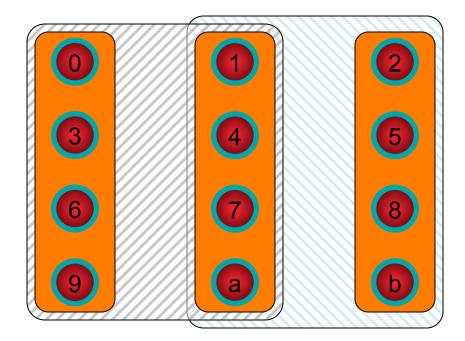

# Example

```
MPI_Comm inter_comm, new_inter_comm;
MPI_Group local_group, group;
int rank = 0;
if( /* left side (ie. a*) */ ) {
 MPI_Comm_group( inter_comm, &local_group);
 MPI_Group_incl( local_group, 1, &rank, &group);
 MPI Group free( &local group );
} else
 MPI_Comm_group( inter_comm, &group );
MPI_Comm_create( inter_comm, group,
                   &new_inter_comm );
MPI_Group_free( &group );
```

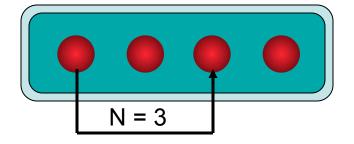

#### Exercice

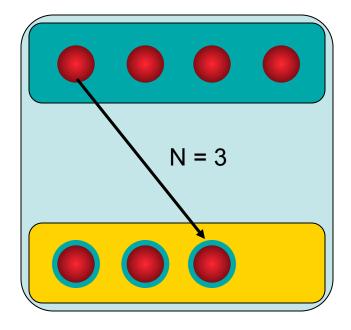

#### Intercommunicators – P2P

On process 0: MPI\_Send( buf, MPI\_INT, 1, n, tag, intercomm )

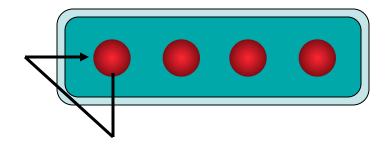

Intracommunicator
 Intercommunicator

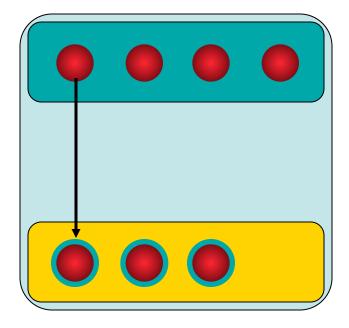

## Intercommunicators—P2P

On process 0: MPI\_Send( buf, MPI\_INT, 1, 0, tag, intercomm )

Not MPI safe if the receive was not posted before.

Intracommunicator
 Intercommunicator

## Communicators - Collectives

- Simple classification by operation class
- One-To-All (simplex mode)
  - One process contributes to the result. All processes receive the result.
    - MPI Bcast
    - MPI\_Scatter, MPI\_Scatterv
- All-To-One (simplex mode)
  - All processes contribute to the result. One process receives the result.
    - · MPI Gather, MPI Gatherv
    - MPI Reduce
- All-To-All (duplex mode)
  - All processes contribute to the result. All processes receive the result.
    - MPI\_Allgather, MPI\_Allgatherv
    - MPI\_Alltoall, MPI\_Alltoallv
    - MPI\_Allreduce, MPI\_Reduce\_scatter
- Other
  - Collective operations that do not fit into one of the above categories.
    - MPI Scan
    - MPI\_Barrier

# Collectives

	Who generate the result	Who receive the result
One-to-all	One in the local group	All in the local group
All-to-one	All in the local group	One in the local group
All-to-all	All in the local group	All in the local group
Others	?	?

## **Extended Collectives**

#### From each process point of view

	Who generate the result	Who receive the result
One-to-all	One in the local group	All in the remote group
All-to-one	All in the local group	One in the remote group
All-to-all	All in the local group	All in the remote group
Others	?	?

#### **Extended Collectives**

- Simplex mode (ie. rooted operations)
  - A root group
    - The root use MPI\_ROOT as root process
    - All others use MPI\_PROC\_NULL
  - A second group
    - All use the real rank of the root in the remote group
- Duplex mode (ie. non rooted operations)
  - Data send by the process in one group is received by the process in the other group and vice-versa.

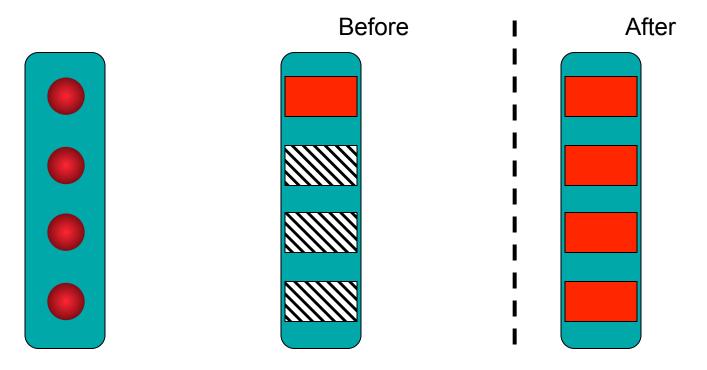

#### Broadcast

One-to-all

One in the local group

One in the local group

MPI\_Bcast( buf, 1, MPI\_INT, 0, intracomm )

#### **Extended Broadcast**

One-to-all

One in the local group

All in the remote group

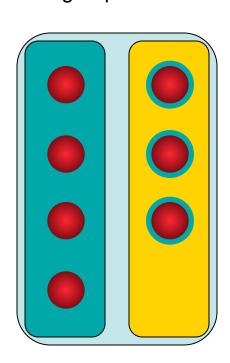

Root group root process:

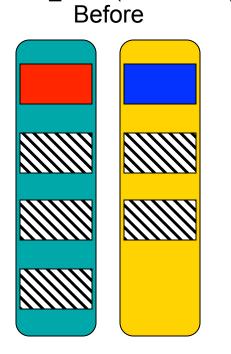

MPI\_Bcast( buf, 1, MPI\_INT, MPI\_ROOT, intercomm )

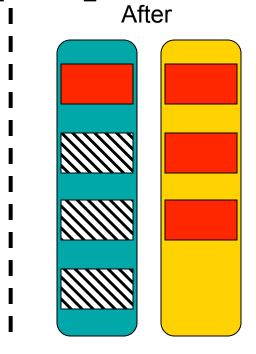

Root group other processes Other group

Root group other processes: MPI\_Bcast( buf, 1, MPI\_INT, MPI\_PROC\_NULL, intercomm )

MPI\_Bcast( buf, 1, MPI\_INT, root\_rank, intercomm )

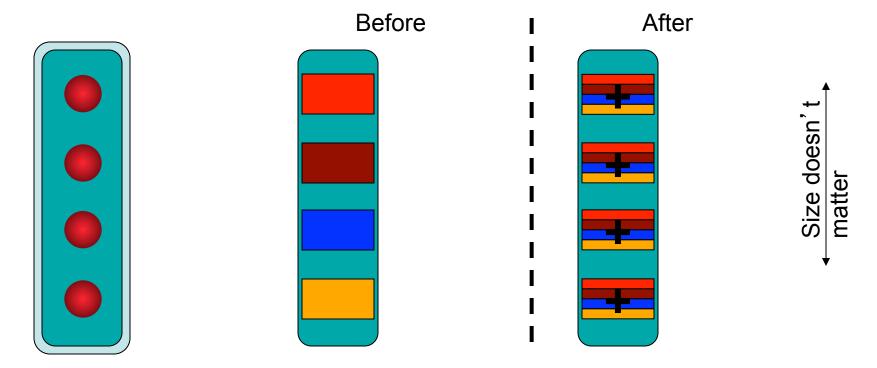

### Allreduce

All-to-all

All in the local group

All in the local group

MPI\_Allreduce( sbuf, rbuf, 1, MPI\_INT, +, intracomm )

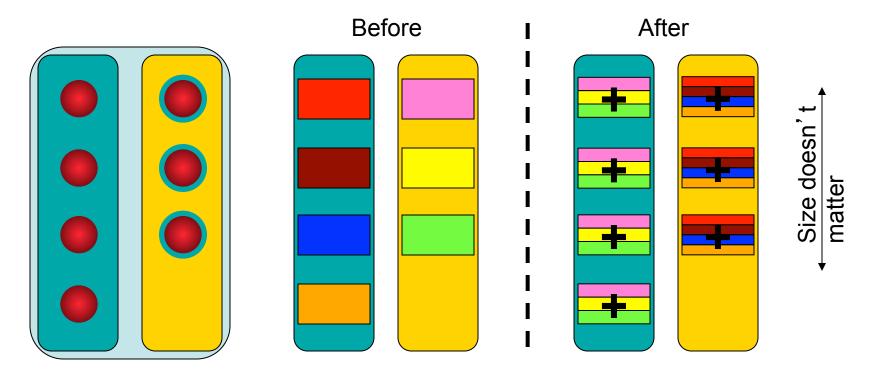

## **Extended Allreduce**

All-to-one

All in the local group

All in the remote group

MPI\_Allreduce( sbuf, rbuf, 1, MPI\_INT, +, intercomm )

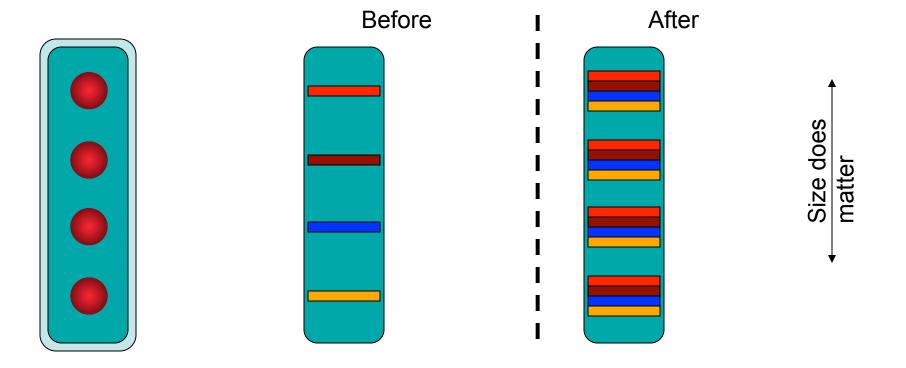

## AllGather

All-to-all

All in the local group

All in the local group

MPI\_Allgather( sbuf, 1, MPI\_INT, rbuf, 1, MPI\_INT, +, intracomm )

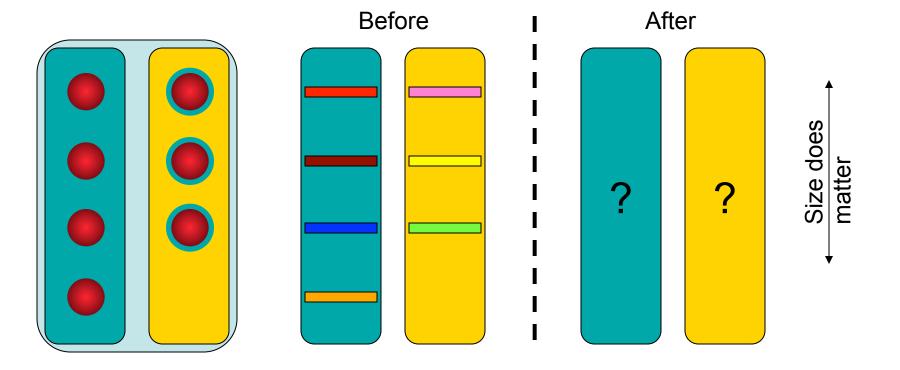

#### Extended AllGather

All-to-all

All in the local group

All in the remote group

MPI\_Allgather( sbuf, 1, MPI\_INT, rbuf, 1, MPI\_INT, +, intercomm )

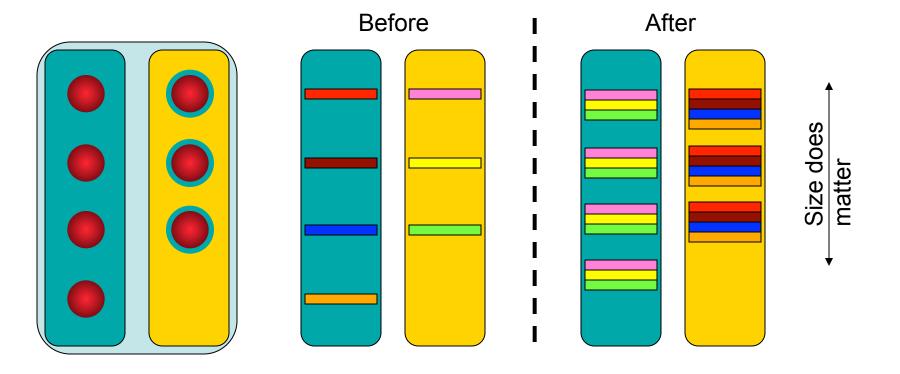

#### Extended AllGather

All-to-all

All in the local group

All in the remote group

MPI\_Allgather( sbuf, 1, MPI\_INT, rbuf, 1, MPI\_INT, +, intercomm )

### Scan/Exscan and Barrier

- Scan and Exscan are illegal on intercommunicators
- For MPI\_Barrier all processes in a group may exit the barrier when all processes on the other group have entered in the barrier.
